

Recommendation App Architecture:

Algorithm:

- Algorithm works on the basis of watchlist.
- This algorithm finds out which movie user has watched and collect the feature of movies like comedy, sci-fi, etc.
- After collecting features of movies watched by user, algorithm search entire movie dataset and match the features of movie watched with the feature of movie in dataset ignoring watched one, then algorithm collects the name of movies and store it in collection like ArrayList.
- After storing it in collection (ArrayList), sorting algorithm is called and movies get sorted on the basis of name.
- And then the list of recommend movies is passed to calling method or API.
